February 25, 2019

Outline

- 1 Recursive Functions
- 2 Recursive Structures
- 3 The Tower of Hanoi

Recursive Functions

A function that calls itself in its body (why?) is a recursive function.

- Directly

```
def is_even(n):  
    return True if n == 0 else not is_even(n-1)
```

- Indirectly

```
def is_even(n):  
    return True if n == 0 else is_odd(n-1)  
  
def is_odd(n):  
    return False if n == 0 else is_even(n-1)
```

Problems and Sub-problems

- Why must a function call itself?
- Some problems can be simplified to sub-problems that have similar or identical structures.
- It's simple to solve the main problem based on the solution of its sub-problems.
 - How can we build a list? If we have a smaller list (a sub-problem) as the tail, then we can add a head node in front of it to build a bigger list.

- We must build the tail list first, in the same way.
- There must be at least a *base case* to terminate the recursion. Solving the base problem does *not* depend on the solution of any sub-problem.

Building a List Recursively

- Suppose we have the *Node* class with a constructor declared below:

```
class Node:
    def __init__(self, elm, nxt):
        self.elm = elm
        self.nxt = nxt
```

- The *build_list* function defined below builds a list of nodes containing integers from *start* to *stop*, and returns the reference to the head node.

```
def build_list(start, stop):
    return None if start >= stop else Node(start, build_list(start+1, stop))
```

- The list shown in Slide 4 can be built by *build_list*(1, 7).

Fibonacci Spiral

The Tower of Hanoi

- We are given a tower of 8 disks, initially stacked in decreasing size on one of three pegs:

- The objective is to transfer the entire tower to one of the other pegs, moving only one disk at a time and never moving a larger one onto a smaller one. (Édouard Lucas, 1883)
- This puzzle can be solved by breaking the problem down into a collection of smaller problems and further breaking those problems down into even smaller problems until a direct solution is reached.

The Tower of Hanoi

- We are given a tower of 8 disks, initially stacked in decreasing size on one of three pegs:

- The objective is to transfer the entire tower to one of the other pegs, moving only one disk at a time and never moving a larger one onto a smaller one. (Édouard Lucas, 1883)
- This puzzle can be solved by breaking the problem down into a collection of smaller problems and further breaking those problems down into even smaller problems until a direct solution is reached.

The Tower of Hanoi

- This puzzle can be solved by breaking the problem down into a collection of smaller problems and further breaking those problems down into even smaller problems until a direct solution is reached.

The Tower of Hanoi

- We are given a tower of 8 disks, initially stacked in decreasing size on one of three pegs:

- The objective is to transfer the entire tower to one of the other pegs, moving only one disk at a time and never moving a larger one onto a smaller one. (Édouard Lucas, 1883)
- This puzzle can be solved by breaking the problem down into a collection of smaller problems and further breaking those problems down into even smaller problems until a direct solution is reached.

Moving Three Disks

A Recursive Solution

We need to construct a method to move n ($n \geq 0$) disks from peg *src* to peg *dest*, using peg *aux* as temporary storage — *moveTower*($n, src, aux, dest$).

- If n is 0, we need to do nothing.
- If n is greater than 0, we can break the task into smaller tasks:
 - ① Move the top $n - 1$ disks from peg *src* to peg *aux*, using peg *dest* as temporary storage — *moveTower*($n - 1, src, dest, aux$).
 - ② Move the bottom disk from peg *src* to peg *dest*.
 - ③ Move the top $n - 1$ disks from peg *aux* to peg *dest*, using peg *src* as temporary storage — *moveTower*($n - 1, aux, src, dest$).

A Recursive Solution

We need to construct a method to move n ($n \geq 0$) disks from peg *src* to peg *dest*, using peg *aux* as temporary storage — *moveTower*($n, src, aux, dest$).

- If n is 0, we need to do nothing.
- If n is greater than 0, we can break the task into smaller tasks:
 - ① Move the top $n - 1$ disks from peg *src* to peg *aux*, using peg *dest* as temporary storage — *moveTower*($n - 1, src, dest, aux$).
 - ② Move the bottom disk from peg *src* to peg *dest*.
 - ③ Move the top $n - 1$ disks from peg *aux* to peg *dest*, using peg *src* as temporary storage — *moveTower*($n - 1, aux, src, dest$).

A Recursive Solution

We need to construct a method to move n ($n \geq 0$) disks from peg *src* to peg *dest*, using peg *aux* as temporary storage — *moveTower*($n, src, aux, dest$).

- If n is 0, we need to do nothing.
- If n is greater than 0, we can break the task into smaller tasks:

The Tower of Hanoi — Code

- The state of the three towers is stored as three stacks of numbers ranging from 1 to n , with larger numbers representing larger disks.
- The steps of transferring the disks are generated as a sequence of snapshots of the intermediate states.

```

1 def hanoi(n):
2     ts = [LnLs(range(1, n+1)), LnLs(), LnLs()]
3     yield [list(t) for t in ts]
4     yield from move_tower(ts, n, *ts)
5 def move_tower(ts, n, src, aux, dest):
6     if n > 0:
7         yield from move_tower(ts, n-1, src, dest, aux)
8         dest.push(src.pop())
9         yield [list(t) for t in ts]
10        yield from move_tower(ts, n-1, aux, src, dest)

```

The Number of Steps

We define the number of steps required for transferring an n -disk tower as

$$\text{steps}(n).$$

- For transferring 0 disk, there is $0 = 2^0 - 1$ step.
- For transferring 1 disk, there is only $1 = 2^1 - 1$ step.
- For transferring 2 disks, there are $1 + 1 + 1 = 3 = 2^2 - 1$ steps.
- For transferring n disks, there are

$$\text{steps}(n-1) + 1 + \text{steps}(n-1) = (2^{n-1} - 1) + 1 + (2^{n-1} - 1) = 2^n - 1$$

steps.
