# COMP223: Software Engineering Design and Implementation

Dr. Kim, Song-Kyoo (Amang)  
Associate Professor,

Computer Science Program  
MACAO POLYTECHNIC INSTITUTE  
Macau, SAR

# Session (Chapter 7) Objectives

- Object-oriented design using the UML
- Design patterns
- Implementation issues
- Open source development

澳門理工學院  
Instituto Politécnico de Macau  
Macao Polytechnic Institute

# Design & Implementation (Part 1)

# Design and implementation (1/2)

- Software design and implementation is the stage in the software engineering process at which an executable software system is developed.
- Software design and implementation activities are invariably inter-leaved.
  - Software design is a creative activity in which you identify software components and their relationships, based on requirements of customers.
  - Implementation is the process of realizing the design as a program.

# Design and implementation (2/2)

## ● Build or buy

- In a wide range of domains, it is now possible to buy off-the-shelf systems (COTS) that can be adapted and tailored to the users' requirements.
- For example, if you want to implement a medical records system, you can buy a package that is already used in hospitals. It can be cheaper and faster to use this approach rather than developing a system in a conventional programming language.
- When you develop an application in this way, the design process becomes concerned with how to use the configuration features of that system to deliver the system requirements.

# Object-oriented design using the UML (1/20)

- An object-oriented design process
  - Structured object-oriented design processes involve developing a number of different system models.
  - They require a lot of effort for development and maintenance of these models and, for small systems, this may not be cost-effective.
  - However, for large systems developed by different groups design models are an important communication mechanism.

# Object-oriented design using the UML (2/20)

- **Process stages**: there are a variety of different object-oriented design processes that depend on the organization using the process.
- Common activities in these processes include:
  - Define the context and modes of use of the system;
  - Design the system architecture;
  - Identify the principal system objects;
  - Develop design models;
  - Specify object interfaces.
- Process illustrated here using a design for a wilderness weather station.

# Object-oriented design using the UML (3/20)

- System context and interactions

- Understanding the relationships between the software that is being designed and its external environment is essential for deciding how to provide the required system functionality and how to structure the system to communicate with its environment.
- Understanding of the context also lets you establish the boundaries of the system. Setting the system boundaries helps you decide what features are implemented in the system being designed and what features are in other associated systems.

# Object-oriented design using the UML (4/20)

## ● Context and interaction models

- A system context model is a structural model that demonstrates the other systems in the environment of the system being developed.
- An interaction model is a dynamic model that shows how the system interacts with its environment as it is used.

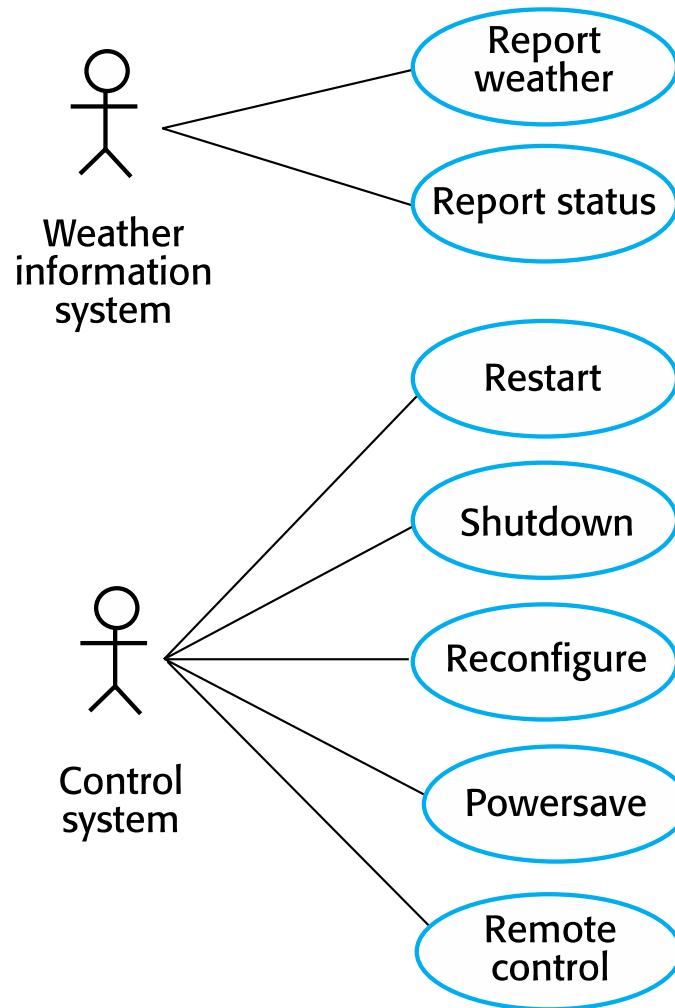

## ● System context for the weather station

# Object-oriented design using the UML (5/20)

## ● Weather station use cases

# Object-oriented design using the UML (6/20)

## ● Use case description—Report weather

System	Weather station
Use case	Report weather
Actors	Weather information system, Weather station
Description	The weather station sends a summary of the weather data that has been collected from the instruments in the collection period to the weather information system. The data sent are the maximum, minimum, and average ground and air temperatures; the maximum, minimum, and average air pressures; the maximum, minimum, and average wind speeds; the total rainfall; and the wind direction as sampled at five-minute intervals.
Stimulus	The weather information system establishes a satellite communication link with the weather station and requests transmission of the data.
Response	The summarized data is sent to the weather information system.
Comments	Weather stations are usually asked to report once per hour but this frequency may differ from one station to another and may be modified in the future.

# Object-oriented design using the UML (7/20)

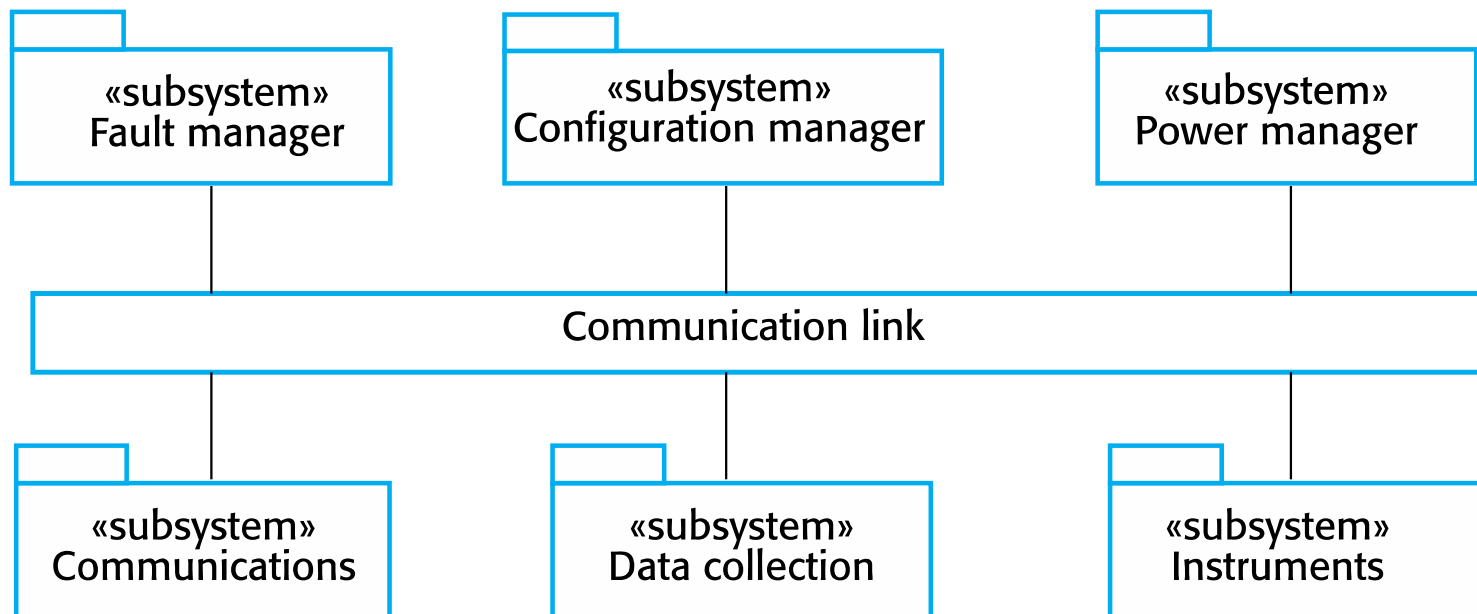

## ● Architectural design

- Once interactions between the system and its environment have been understood, you use this information for designing the system architecture.
- You identify the major components that make up the system and their interactions, and then may organize the components using an architectural pattern such as a layered or client-server model.
- The weather station is composed of independent subsystems that communicate by broadcasting messages on a common infrastructure.

# Object-oriented design using the UML (8/20)

- High-level architecture of the weather station

# Object-oriented design using the UML (9/20)

- Architecture of data collection system

# OOD using the UML (10/20)

## ● Object class identification

- Identifying object classes is often a difficult part of object oriented design.
- There is no 'magic formula' for object identification.
- It relies on the skill, experience and domain knowledge of system designers.
- Object identification is an iterative process.
- You are unlikely to get it right first time.

# OOD using the UML (11/20)

- **Weather station object classes:** object class identification in the weather station system may be based on the tangible hardware and data in the system:
- Ground thermometer, Anemometer, Barometer
  - Application domain objects that are 'hardware' objects related to the instruments in the system.
- Weather station
  - The basic interface of the weather station to its environment. It therefore reflects the interactions identified in the use-case model.
- Weather data
  - Encapsulates the summarized data from the instruments.

# OOD using the UML (12/20)

- Weather station object classes

WeatherStation
identifier
reportWeather () reportStatus () powerSave (instruments) remoteControl (commands) reconfigure (commands) restart (instruments) shutdown (instruments)

WeatherData
airTemperatures groundTemperatures windSpeeds windDirections pressures rainfall
collect () summarize ()

Ground thermometer
gt_Ident temperature
get () test ()

Anemometer
an_Ident windSpeed windDirection
get () test ()

Barometer
bar_Ident pressure height
get () test ()

# OOD using the UML (13/20)

- **Design models** show the objects and object classes and relationships between these entities.
- There are two kinds of design model:
  - **Structural models** describe the static structure of the system in terms of object classes and relationships.
  - **Dynamic models** describe the dynamic interactions between objects.

# OOD using the UML (14/20)

- Examples of design models
  - Subsystem models that show logical groupings of objects into coherent subsystems.
  - Sequence models that show the sequence of object interactions.
  - State machine models that show how individual objects change their state in response to events.
  - Other models include use-case models, aggregation models, generalization models, etc.

# OOD using the UML (15/20)

- **Subsystem models** shows how the design is organized into logically related groups of objects.
  - In the UML, these are shown using packages - an encapsulation construct.
  - This is a logical model.
  - The actual organization of objects in the system may be different.

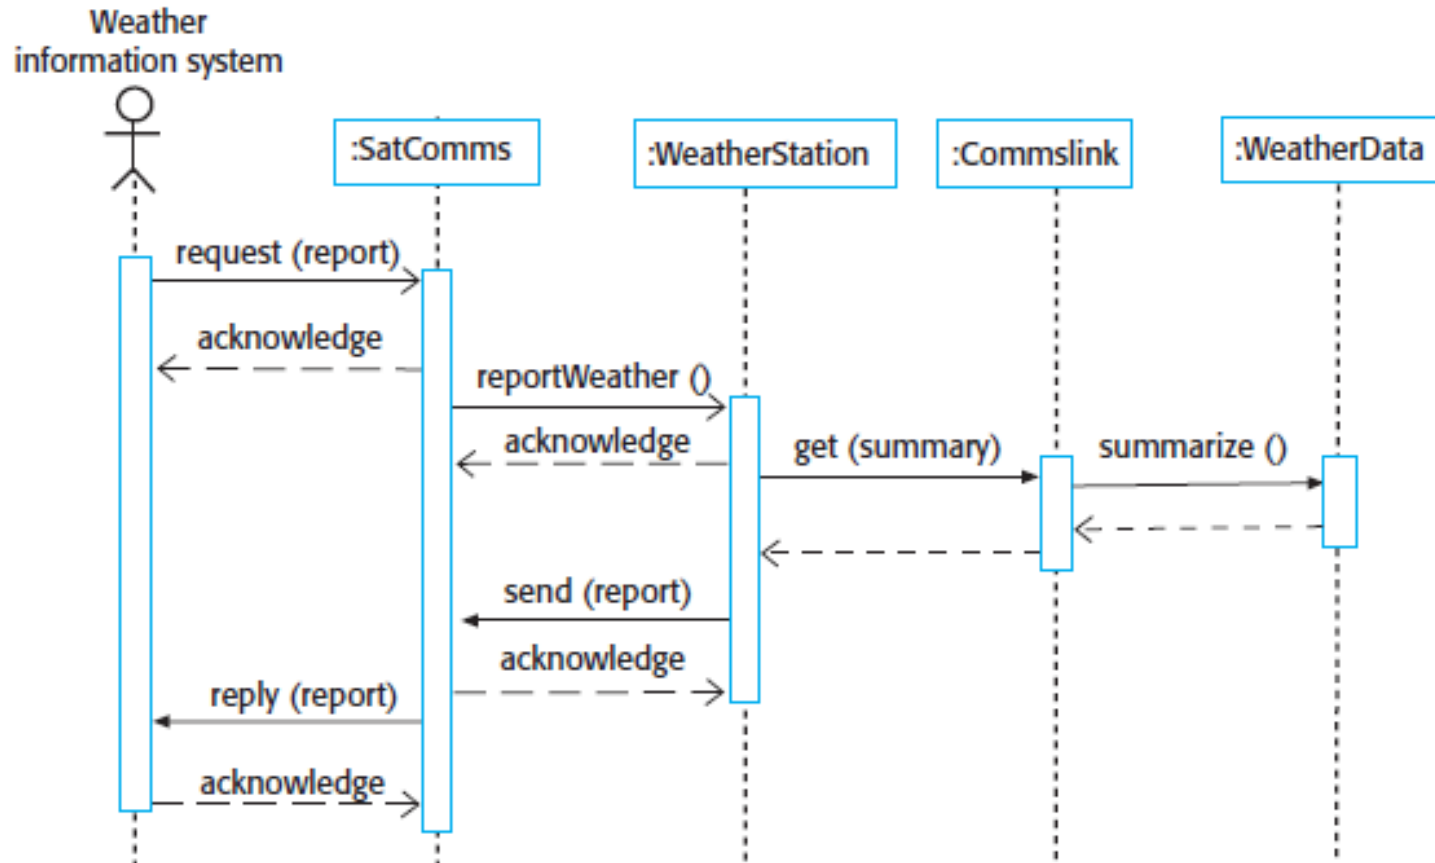

# OOD using the UML (16/20)

- **Sequence models** show the sequence of object interactions that take place.
  - Objects are arranged horizontally across the top;
  - Time is represented vertically so models are read top to bottom;
  - Interactions are represented by labelled arrows, Different styles of arrow represent different types of interaction;
  - A thin rectangle in an object lifeline represents the time when the object is the controlling object in the system.

# OOD using the UML (17/20)

- Sequence diagram describing data collection

# OOD using the UML (18/20)

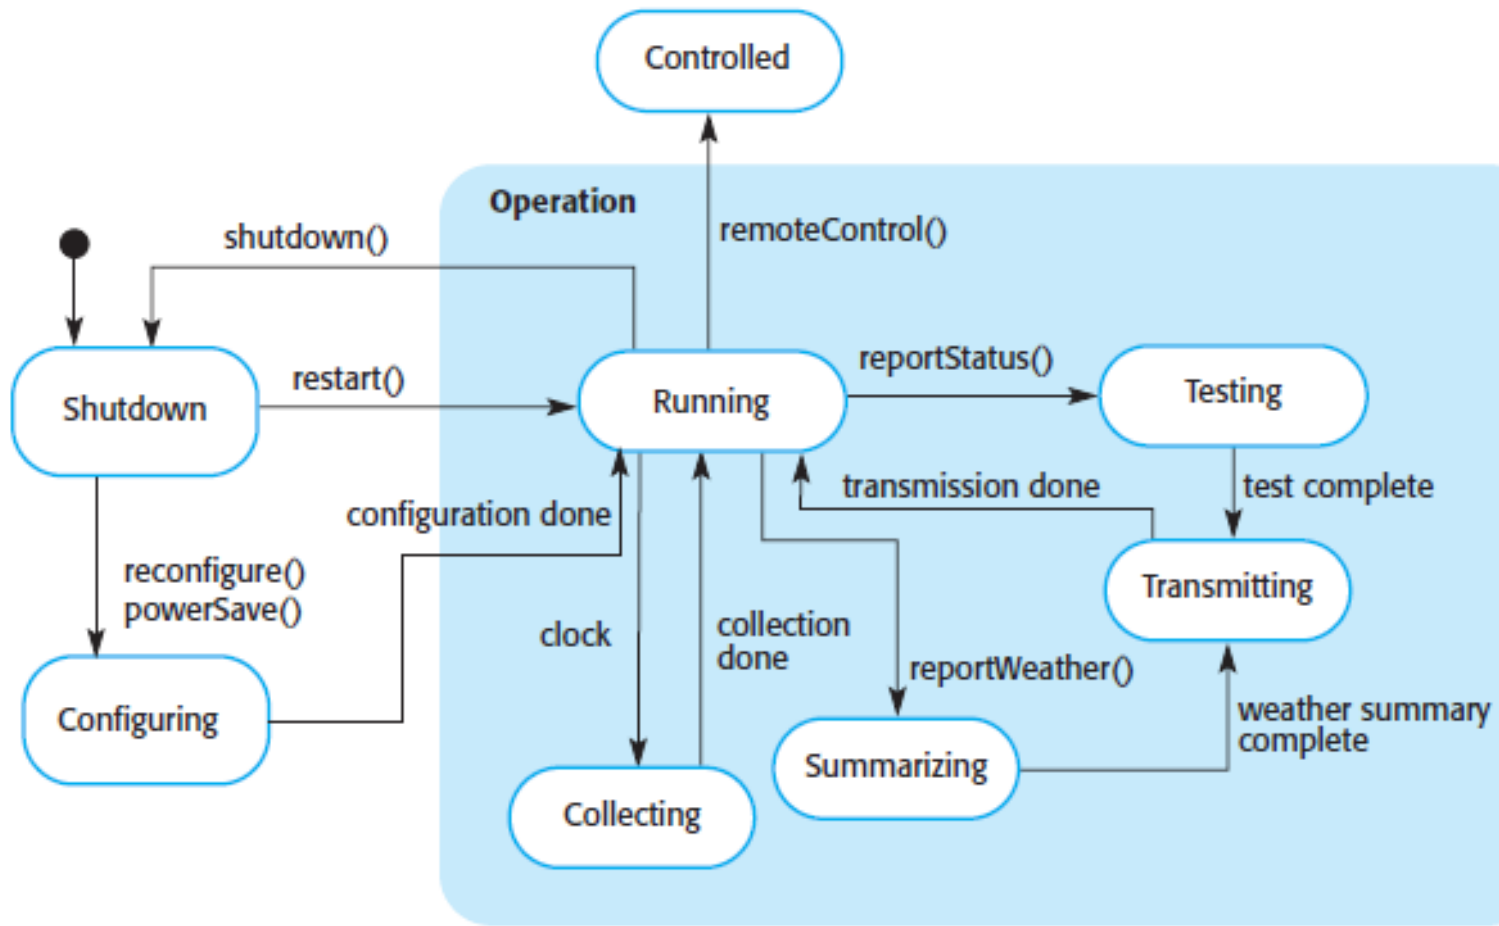

- **State diagrams** are used to show how objects respond to different service requests and the state transitions triggered by these requests.
- State diagrams are useful high-level models of a system or an object's run-time behavior.
- You do not usually need a state diagram for all of the objects in the system.
- Many of the objects in a system are relatively simple and a state model adds unnecessary detail to the design.

# OOD using the UML (19/20)

- Weather station state diagram

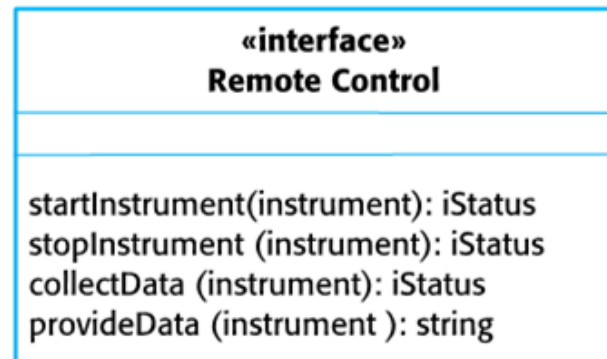

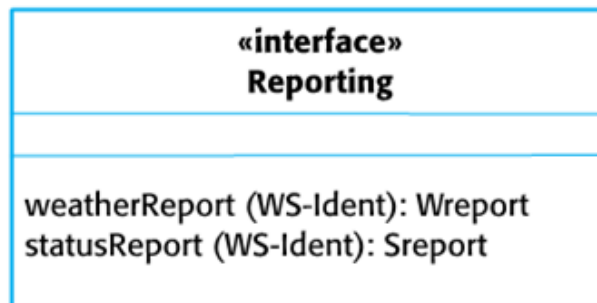

# OOD design using the UML (20/20)

## ● Interface specification:

- Object interfaces have to be specified so that the objects and other components can be designed in parallel.
- Designers should avoid designing the interface representation but should hide this in the object itself.
- Objects may have several interfaces which are viewpoints on the methods provided.

## ● Weather station interfaces

# Design & Implementation (Part 2)

# Design patterns (1/6)

- **A design pattern** is a way of reusing abstract knowledge about a problem and its solution.
- A pattern is a description of the problem and the essence of its solution.
- It should be sufficiently abstract to be reused in different settings.
- Pattern descriptions usually make use of object-oriented characteristics such as inheritance and polymorphism.

# Design patterns (2/6)

- **Patterns and Pattern Languages:** the ways to describe best practices, good designs, and capture experience in a way that it is possible for others to reuse this experience.
  
- **Pattern elements**
  - **Name:** A meaningful pattern identifier.
  - **Problem description.**
  - **Solution description.**
    - Not a concrete design but a template for a design solution that can be instantiated in different ways.
  - **Consequences**
    - The results and trade-offs of applying the pattern.

# Design patterns (3/6)

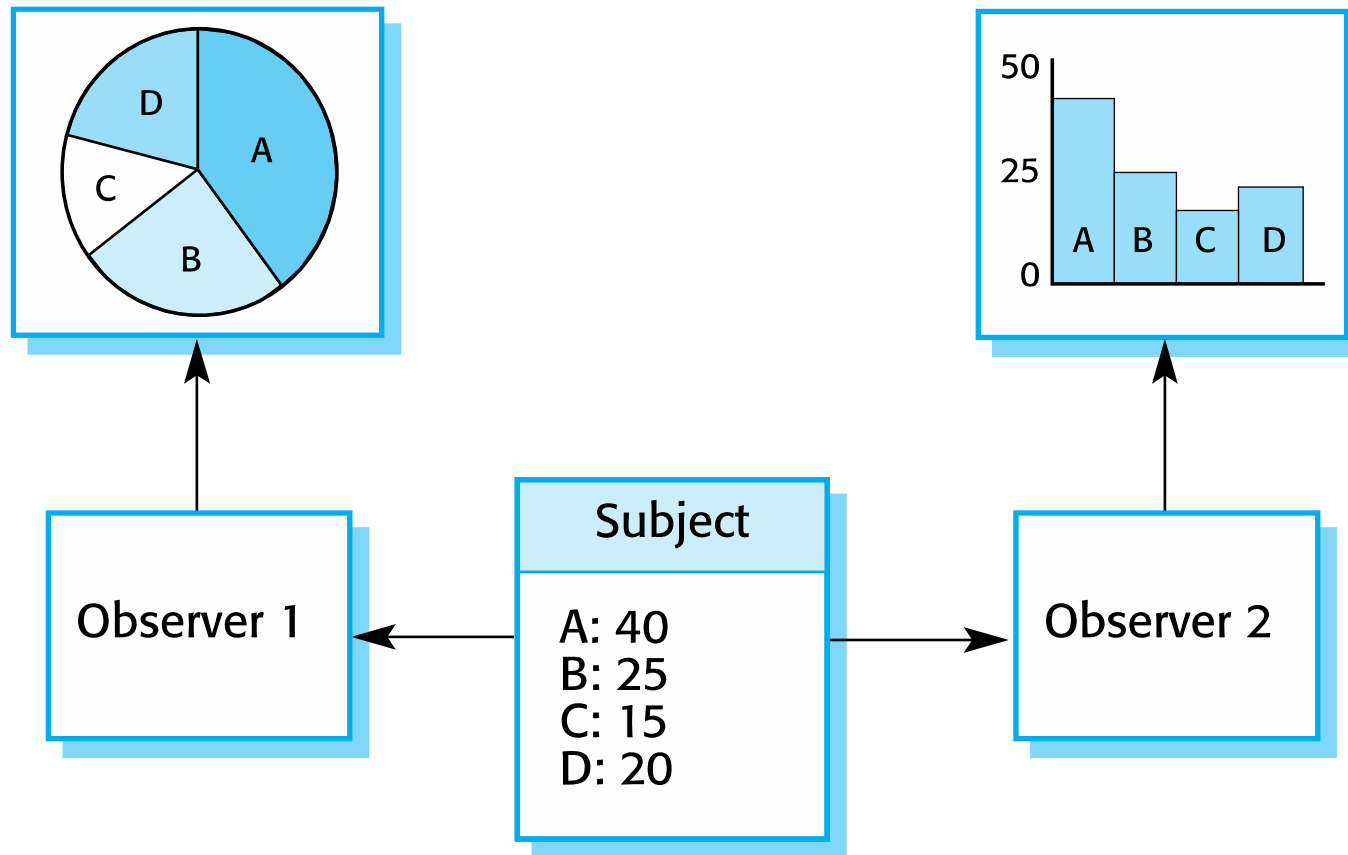

## ● The Observer pattern (1)

Pattern name	Observer
Description	<p>Separates the display of the state of an object from the object itself and allows alternative displays to be provided.</p> <p>When the object state changes, all displays are automatically notified and updated to reflect the change.</p>
Problem description	<p>In many situations, you have to provide multiple displays of state information, such as a graphical display and a tabular display. Not all of these may be known when the information is specified. All alternative presentations should support interaction and, when the state is changed, all displays must be updated.</p> <p>This pattern may be used in all situations where more than one display format for state information is required and where it is not necessary for the object that maintains the state information to know about the specific display formats used.</p>

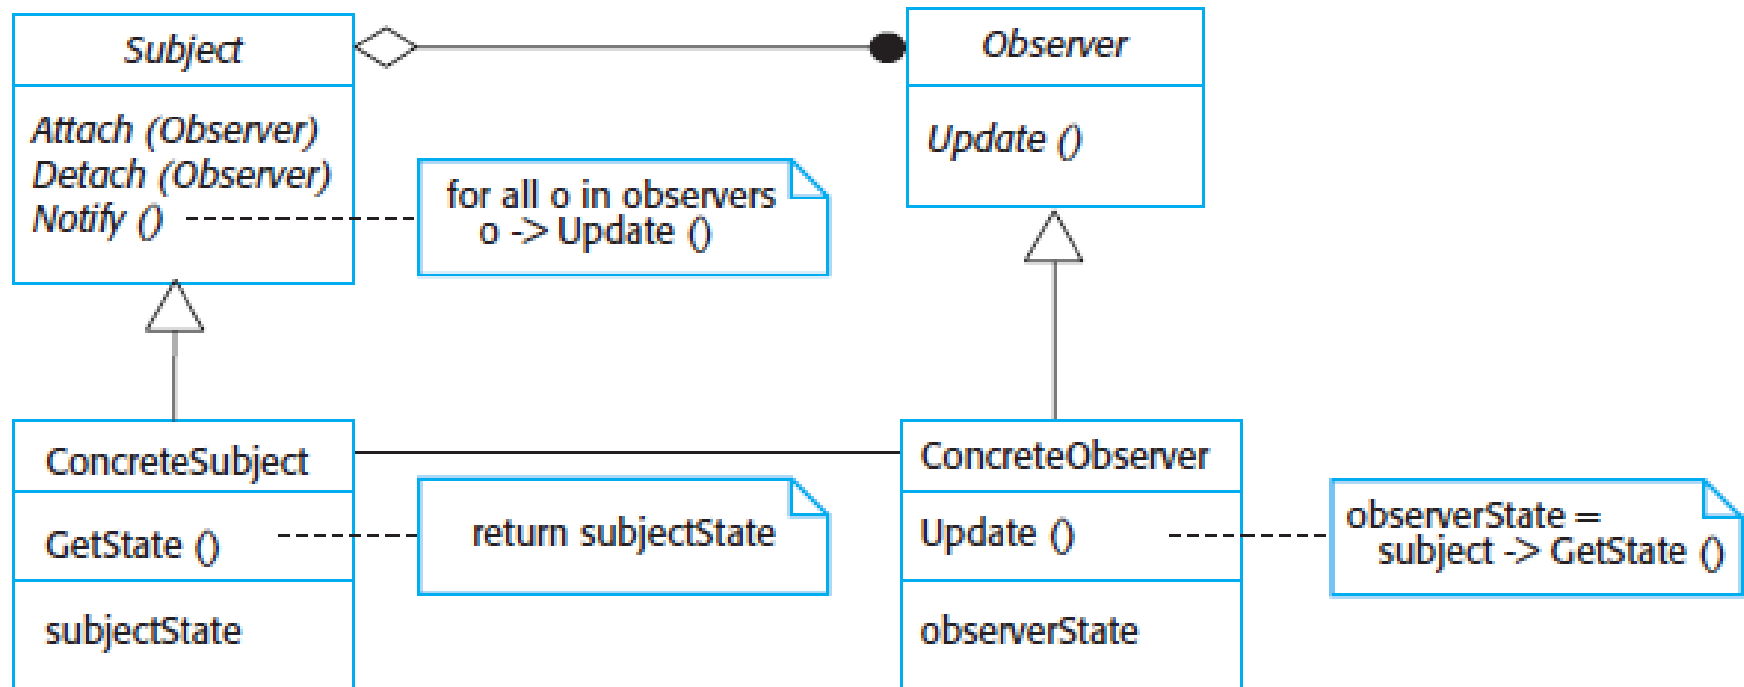

# Design patterns (4/6)

- Multiple displays using the Observer pattern

# Design patterns (5/6)

- A UML (Unified Modeling Language) model of the Observer pattern

# Design patterns (6/6)

## ● Design problems:

- Observer pattern: tell several objects that the state of some other object has changed.
- Façade pattern: tidy up the interfaces to a number of related objects that have often been developed incrementally.
- Iterator pattern: provide a standard way of accessing the elements in a collection, irrespective of how that collection is implemented.
- Decorator pattern: allow for the possibility of extending the functionality of an existing class at run-time.

# Implementation issues (1/16)

- Focus here is not on programming, although this is obviously important, but on other implementation issues that are often not covered in programming texts:
- **Reuse Most modern software** is constructed by reusing existing components or systems.
- When you are developing software, you should make as much use as possible of existing code.

# Implementation issues (2/16)

- **Configuration management** During the development process, you have to keep track of the many different versions of each software component in a configuration management system.
- **Host-target development** **Production software** does not usually execute on the same computer as the software development environment.
- Rather, you develop it on one computer (the host system) and execute it on a separate computer (the target system).

# Implementation issues (3/16)

## ● Reuse

- From the 1960s to the 1990s, most new software was developed from scratch, by writing all code in a high-level programming language.
  - The only significant reuse or software was the reuse of functions and objects in programming language libraries.
- Costs and schedule pressure mean that this approach became increasingly unviable, especially for commercial and Internet-based systems.
- An approach to development based around the reuse of existing software emerged and is now generally used for business and scientific software.

# Implementation issues (4/16)

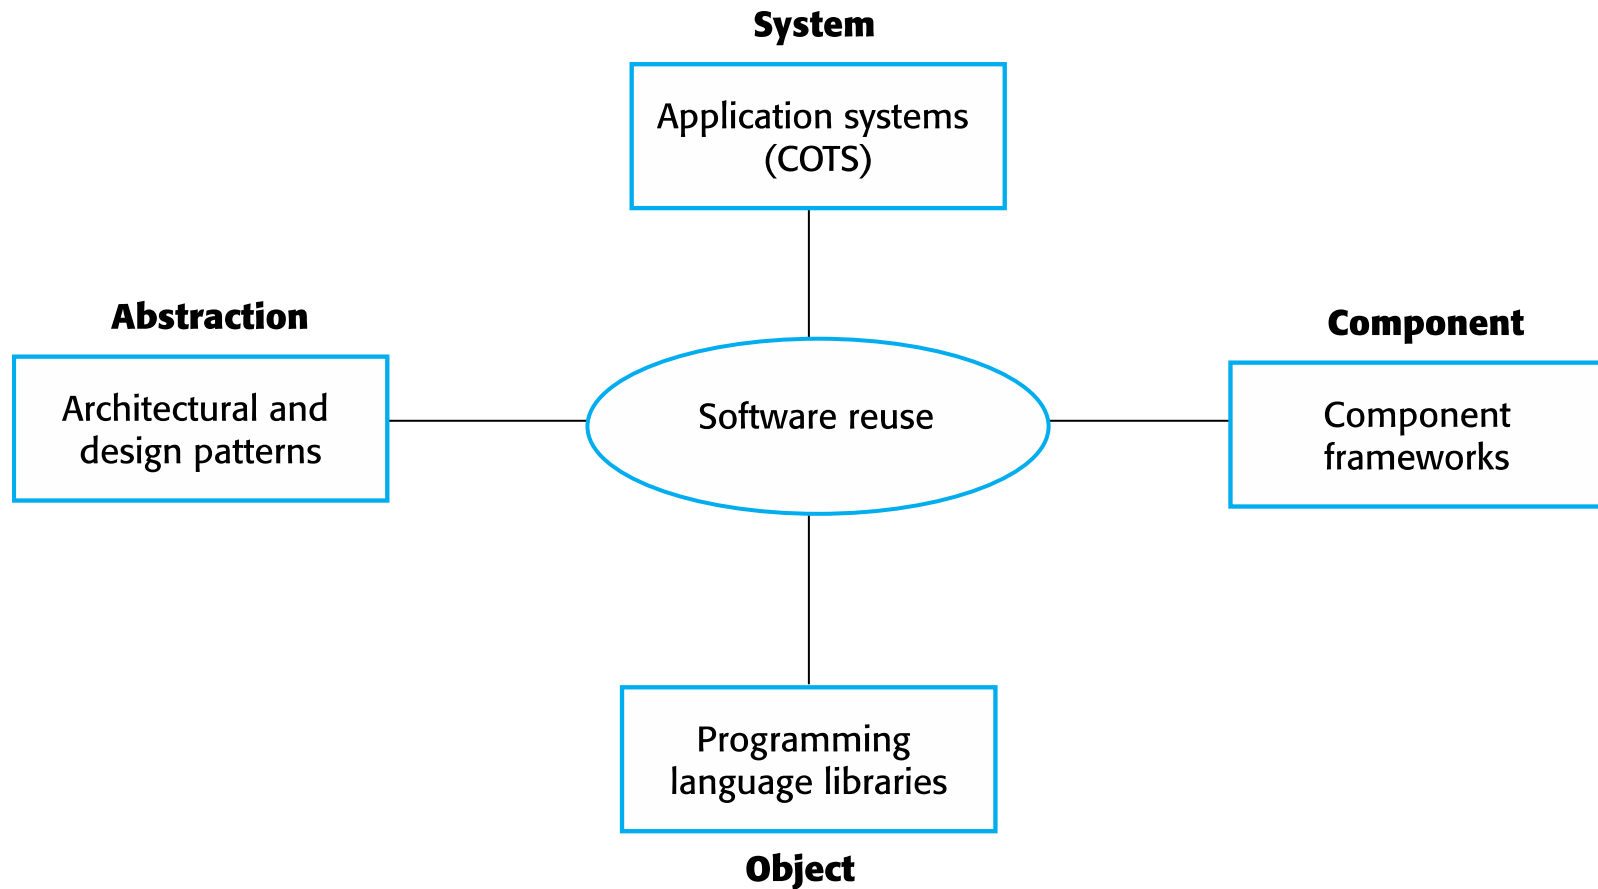

## ● Reuse levels

- The abstraction level: at this level, you don't reuse software directly but use knowledge of successful abstractions in the design of your software.
- The object level: at this level, you directly reuse objects from a library rather than writing the code yourself.
- The component level: components are collections of objects and object classes that you reuse in application systems.
- The system level: at this level, you reuse entire application systems.

# Implementation issues (5/16)

- Software reuse

# Implementation issues (6/16)

## ● Reuse costs

- The costs of the time spent in looking for software to reuse and assessing whether or not it meets your needs.
- Where applicable, the costs of buying the reusable software. For large off-the-shelf systems, these costs can be very high.
- The costs of adapting and configuring the reusable software components or systems to reflect the requirements of the system that you are developing.
- The costs of integrating reusable software elements with each other (if you are using software from different sources) and with the new code that you have developed.

# Implementation issues (7/16)

- **Configuration management** is the name given to the general process of managing a changing software system.
- The aim of configuration management is to support the system integration process so that all developers can access the project code and documents in a controlled way, find out what changes have been made, and compile and link components to create a system.

# Implementation issues (8/16)

## ● Configuration management activities:

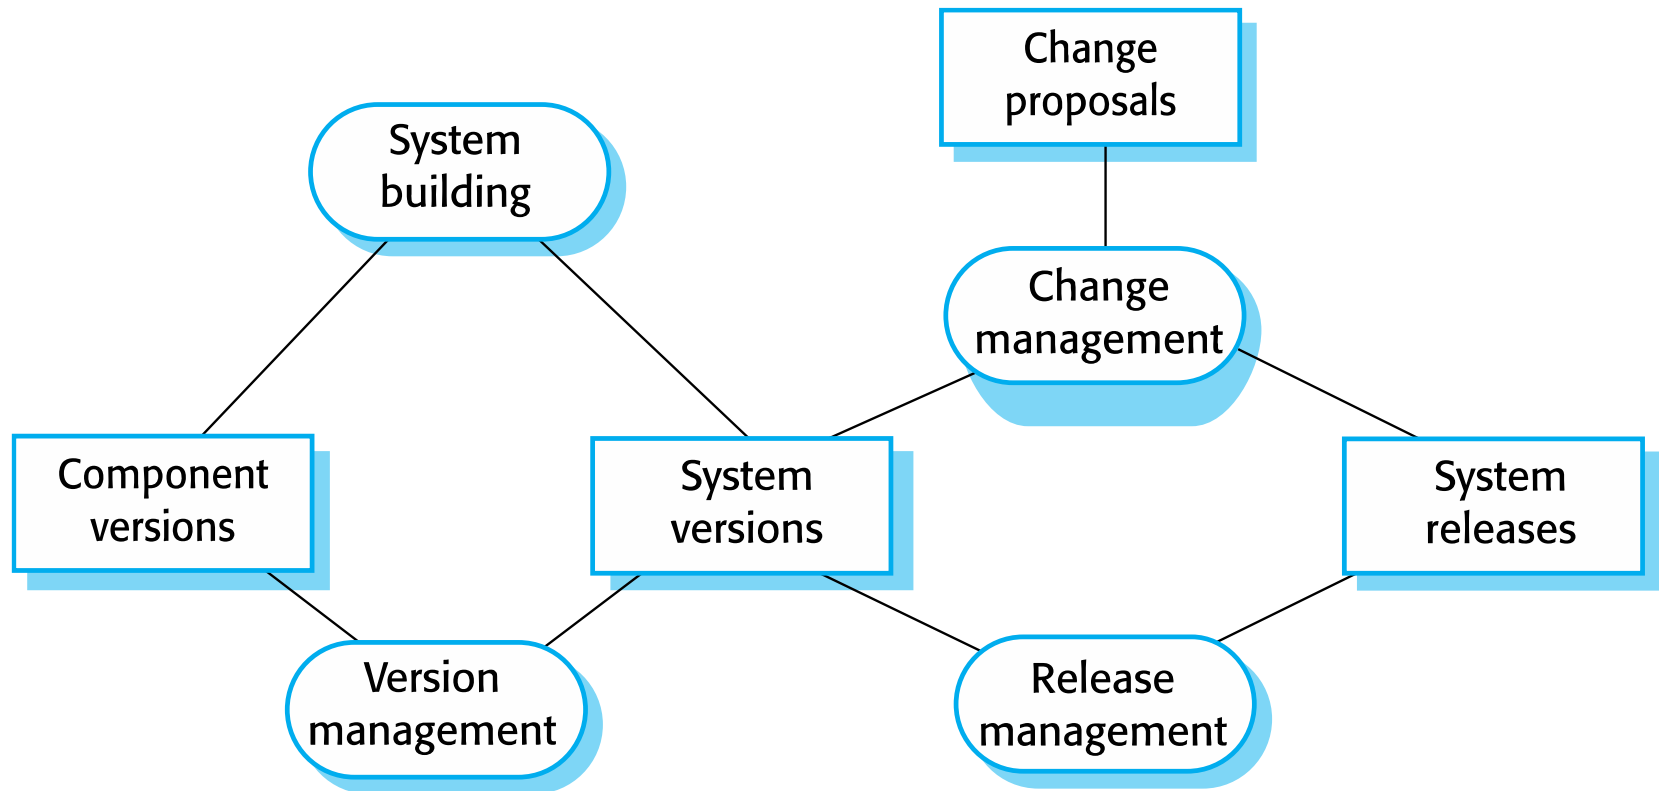

- Version management, where support is provided to keep track of the different versions of software components.
- Version management systems include facilities to coordinate development by several programmers.
- System integration, where support is provided to help developers define what versions of components are used to create each version of a system.
- This description is then used to build a system automatically by compiling and linking the required components.
- Problem tracking, where support is provided to allow users to report bugs and other problems, and to allow all developers to see who is working on these problems and when they are fixed.

# Implementation issues (9/16)

- Configuration management tool interaction

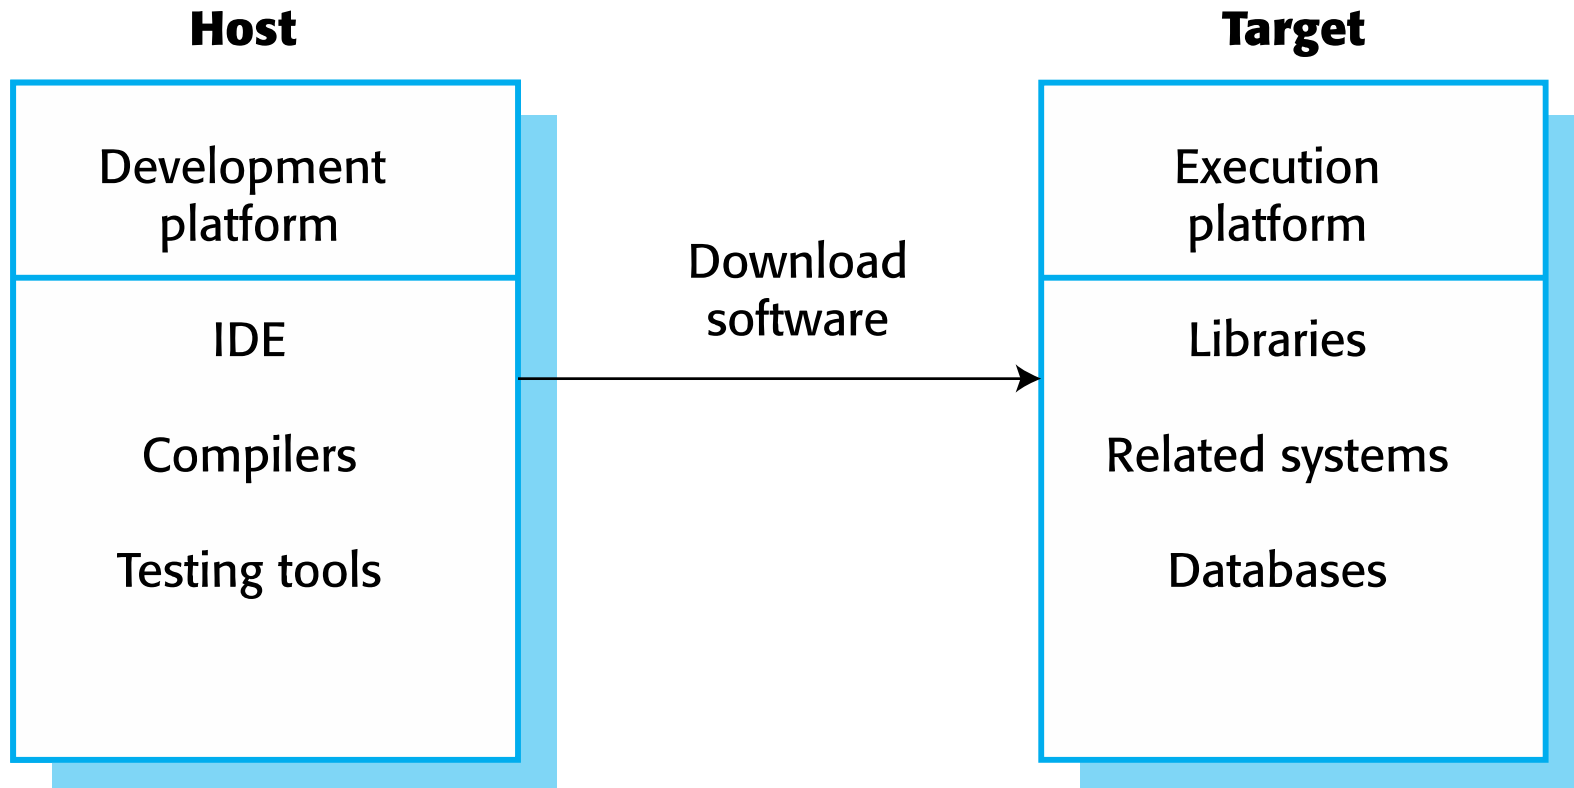

# Implementation issues (10/16)

- Host-target development: Most software is developed on one computer (the host), but runs on a separate machine (the target).
  - More generally, we can talk about a development platform and an execution platform.
  - A platform is more than just hardware.
  - It includes the installed operating system plus other supporting software such as a database management system or, for development platforms, an interactive development environment.
- Development platform usually has different installed software than execution platform; these platforms may have different architectures.

# Implementation issues (12/16)

- Host-target development

# Implementation issues (13/16)

## ● Development platform tools

- An integrated compiler and syntax-directed editing system that allows you to create, edit and compile code.
- A language debugging system.
- Graphical editing tools, such as tools to edit UML models.
- Testing tools, such as Junit that can automatically run a set of tests on a new version of a program.
- Project support tools that help you organize the code for different development projects.

# Implementation issues (14/16)

- Integrated development environments (IDEs)
  - Software development tools are often grouped to create an integrated development environment (IDE).
  - An IDE is a set of software tools that supports different aspects of software development, within some common framework and user interface.
  - IDEs are created to support development in a specific programming language such as Java.
  - The language IDE may be developed specially, or may be an instantiation of a general-purpose IDE, with specific language-support tools.

# Implementation issues (15/16)

- Component/system deployment factors
  - If a component is designed for a specific hardware architecture, or relies on some other software system, it must obviously be deployed on a platform that provides the required hardware and software support.
  - High availability systems may require components to be deployed on more than one platform.
  - This means that, in the event of platform failure, an alternative implementation of the component is available.

# Implementation issues (16/16)

- Component/system deployment factors (cont.)
  - If there is a high level of communications traffic between components, it usually makes sense to deploy them on the same platform or on platforms that are physically close to one other.
  - This reduces the delay between the time a message is sent by one component and received by another.

# Open source development (1/7)

- Open source development is an approach to software development in which the source code of a software system is published and volunteers are invited to participate in the development process
- Its roots are in the Free Software Foundation ([www.fsf.org](http://www.fsf.org)), which advocates that source code should not be proprietary but rather should always be available for users to examine and modify as they wish.
- Open source software extended this idea by using the Internet to recruit a much larger population of volunteer developers.

# Open source development (2/7)

## ● Open source systems

- The best-known open source product is, of course, the Linux operating system which is widely used as a server system and, increasingly, as a desktop environment.
- Other important open source products are Java, the Apache web server and the MySQL database management system.

# Open source development (3/7)

## ● Open source business

- More and more product companies are using an open source approach to development.
- Their business model is not reliant on selling a software product but on selling support for that product.
- They believe that involving the open source community will allow software to be developed more cheaply, more quickly and will create a community of users for the software.

# Open source development (4/7)

## ● Open source licensing

- A fundamental principle of open-source development is that source code should be freely available, this does not mean that anyone can do as they wish with that code.
- Legally, the developer of the code (either a company or an individual) still owns the code.
- They can place restrictions on how it is used by including legally binding conditions in an open source software license.

# Open source development (5/7)

- Open source licensing (cont.)
  - Some open source developers believe that if an open source component is used to develop a new system, then that system should also be open source.
  - Others are willing to allow their code to be used without this restriction.
  - The developed systems may be proprietary and sold as closed source systems.

# Open source development (6/7)

## ● License models

- The GNU General Public License (GPL). This is a so-called 'reciprocal' license that means that if you use open source software that is licensed under the GPL license, then you must make that software open source.
- The GNU Lesser General Public License (LGPL) is a variant of the GPL license where you can write components that link to open source code without having to publish the source of these components.
- The Berkley Standard Distribution (BSD) License. This is a non-reciprocal license, which means you are not obliged to re-publish any changes or modifications made to open source code. You can include the code in proprietary systems that are sold.

# Open source development (7/7)

## ● License management

- Establish a system for maintaining information about open-source components that are downloaded and used.
- Be aware of the different types of licenses and understand how a component is licensed before it is used.
- Be aware of evolution pathways for components.
- Educate people about open source.
- Have auditing systems in place.
- Participate in the open source community.

# Session Summary (1/4)

- Software design and implementation are inter-leaved activities.
- The level of detail in the design depends on the type of system and whether you are using a plan-driven or agile approach.
- The process of object-oriented design includes activities to design the system architecture, identify objects in the system, describe the design using different object models and document the component interfaces.

## Session Summary (2/4)

- A range of different models may be produced during an object-oriented design process.
- These include static models (class models, generalization models, association models) and dynamic models (sequence models, state machine models).
- Component interfaces must be defined precisely so that other objects can use them.
- A UML interface stereotype may be used to define interfaces.

# Session Summary (3/4)

- When developing software, you should always consider the possibility of reusing existing software, either as components, services or complete systems.
- Configuration management is the process of managing changes to an evolving software system. It is essential when a team of people are cooperating to develop software.

# Session Summary (4/4)

- Most software development is host-target development.
- You use an IDE on a host machine to develop the software, which is transferred to a target machine for execution.
- Open source development involves making the source code of a system publicly available.
- This means that many people can propose changes and improvements to the software.
